Organic Management Options for the Japanese Beetle

Austen Dudenhoeffer
Area Educator: IPM
Lincoln University
IPM program
Jefferson City, MO 65102
1) A good insect is called a ____ and bad insect is a ____?
2) T/F: Most insects are beneficial
3) Which one is the “true” Japanese beetle?
1) *Popillia japonica*: Native to Japan/China
2) Imported accidently to Riverton, New Jersey, 1916
3) Univoltine in Missouri (1 generation per year)
4) Holometabolous (complete metamorphosis)
5) Females: Rounded tibia   Males: Pointed tibia
Not a concern 10-15 years ago

JB in 30 eastern states (except Florida)

Moving west: Oklahoma

Canada, Russia, and Portugal

Purdue Survey Map: PestTracker CERIS 2015
http://pest.ceris.purdue.edu/services/map/mapNew.php?code=INBPAZA#
1) After mating, female JB deposit 40-60 eggs 5-7 cm deep (July)
2) After 2 weeks, eggs hatch. By September, 3rd instar (2.5 cm)
3) 9 months underground feeding. Pupate 2-3 weeks.
4) Adults emerge June & July, live 30-45 days, die in August
Ecological Significance

1) Generalist feeder >300 species (few predators)
2) Cause damage as larvae and adults
3) Economic Impacts: >$450 million annual prevention (USDA, APHIS)
4) Physical damage: turf, ornamentals, and crops
JB will eat leaf tissue, flower petals, corn silk, and even fruit.

**Common host plants of Japanese beetle**

**Adults**
- oak (*Quercus*)
- elm (*Ulmus*)
- maple (*Acer*)
- grape (*Vitis*)
- peach, cherry, apricot, plum (*Prunus* spp.)
- apple (*Malus*)
- linden (*Tilia*)
- rose (*Rosa*)
- *Zinnia* spp.
- *Dahlia* spp.
- corn (*Zea mays*)
- *Asparagus officinalis*

**Grubs**
- roots of turf grass
- roots of ornamental plants
- soybean (*Glycine max*)
- tomato (*Solanum lycopersicum*)
- hops (*Humulus lupulus*)
- blueberries, blackberries, raspberries (*Rubus* spp.)
Organic Control Options

1) Hand removal (scouts, time consuming, impractical?)
2) Biological control agents (parasitoids, nematodes, & pathogens)
3) Organic Insecticides (OMRI approved materials)
4) Mass Trapping (traps as means of control?)

Tiphia vernalis

PyGanic

Crop Protection EC 1.4%
Parasitoids and Pathogens:

1) Spring Tiphiia (*Tiphiia vernalis*) & Winsome Fly (*Istocheta aldrichi*)
2) Released & established in USA—not commercially available
3) Winsome fly: lays eggs on JB adults, kills in 5-6 days, no JB reproduce
4) Connecticut, Rhode Island, and New England: >20% JB decrease
5) Spring Tiphiia: lays eggs on JB larvae (61% reduction in Connecticut)
6) 120,000 shipped to US by 1933. Ohio, N. Carolina, New Jersey
1) Most popular biological control — no harm to bees, pets, or children
2) Cost: expensive, difficult to produce, early instars mid-July 65°F
3) 2-3 years to establish population — lasts up to 10 years in soil
4) Turf protection: mortality after ingestion= 7 to 21 days
5) Kills 1\textsuperscript{st} & 2\textsuperscript{nd} instar grubs (July)-- 3\textsuperscript{rd} instars more difficult to kill (September)
6) Requires host to reproduce — do not use with lawn pesticides
7) Treats ground where applied — not incoming pressure (5 mi flight!)
8) Can be used in combination with nematodes
Issues with milky spore:

“P. popilliae-based products have been expensive, with only small quantities available. This, along with a history of inconsistent performance against P. japonica, has limited the use of this pathogen....” Koppenhofer and Fuzy (2002)

“Application of a full dose of spore powder . . . failed to induce milky disease in grub populations in soil directly beneath the treated turf . . . We challenge the evidence that commercially available spore powder, applied according to conventional methods, is effective for suppressing localized grub populations” Potter and Redmond (1995)

2 billion spores per kg= 39-40% mortality
4 billion spores per kg= 74-78% mortality

St. Gabriel Organics= 100 million spores per gram
Each infected grub produces billions of spores
Entomopathogenic nematodes

Beneficial Nematodes are live microscopic organisms (non-segmented round worms) that occur naturally in soil.

NemaSeek™ - Hb Beneficial Nematodes

*Heterorhabditis bacteriophora*

Seeks Out Stationary Pests including Grubs, root zone weevils, citrus weevils, Japanese beetles, black vine weevils, ticks, queen ants/termites and more. Great for gardens, lawns, fields, pastures and orchards.

JB Larvae Parasitized by Nematodes

**Heterorhabditis bacteriophora**

- 1 billion juveniles/acre
- 1st JB instar = 75-97% mortality
- 2nd JB instar = 53-88% mortality
- 3rd JB instar = 0-33% mortality

(Power K.T. et al. 2009)

1) Will not harm mammals, birds, or aquatic life
2) Can be stored 2 weeks in refrigerator (no water)
3) Mix with water to apply (backpack sprayer)—spread evenly
4) 2 applications—7 days apart (soil temperature >44°F)
5) Ground needs to stay moist (water every 3-4 days)
6) “entomopathogenic” penetrate body wall/openings
7) Kill JB larvae in 24-48 hrs, 2-4 week max effect (late July)
8) Nematodes mostly die in winter—reapply annually
OMRI-listed insecticides

**Azera Insecticide**

OMRI-listed insecticides [cont’d]

- Microbial-based insecticide
- Spinosad is a fast-acting, somewhat broad-spectrum material that acts on the insect primarily through ingestion, or by direct contact with a spray droplet or a newly treated surface.

Spinosad residues on the leaf surface are broken down by sunlight. Half-lives for spinosyn A (active ingredient) are 2 to 16 days depending on the amount of sunlight received.
But, how effective are organic insecticides?

“Monterey 70% Neem Oil and Garlic Barrier, did not show statistically significant mortality of Japanese beetle or reduce leaf damage.”

“Japanese beetle mortality was low (15%) on Pygenic (1.4% Pyrethrin)-treated leaves, but leaf damage (51%) was reduced.”

“. . .Conserve SC (11.6% spinosad) did not show significant mortality. In contrast, professional products containing pyrethroids resulted in significant mortality to Japanese beetles.”

Hi Dr Pinero. Thank you for your insight and resources last week. I applied Azera to all four groups of peaches, and Azera and Surround to three of the four areas, containing the younger peaches/further from harvest. As I applied product I had many many beetles falling to the ground. The following morning at 10am I saw very few beetles on the trees, and moderate traffic in the air around the trees and in the traps. By noon however the entire four areas and all points in between were swarming with beetles. By 2pm there were as many beetles in clusters on the trees in all four groups, as if I had not applied anything. It is my impression that the
Can mass trapping be used to control Japanese beetles organically?
Early Designs Not Effective for Mass Trapping

1. Commercial traps for monitoring
2. Problems: lure, panels, color, capacity, & number of traps deployed
3. Result: spillover effect/frustration
4. More harm than good?

The proto-type worked great, but required maintenance + it was frequently damaged by animals.
“The Japanese beetle Terminator 3,000”
2015-2016 studies at Carver Farm

- Non-ventilated bin
- Standard trap: yellow top with steel mesh netting sock
- Ventilated bin (window covered by metallic screen)
New low-maintenance design

Ventilation is important!
**RESULTS**  In the 2015 study, the standard trap captured significantly more JB than the non-ventilated bin (ANOVA, $F_{2,56} = 3.9, P = 0.027$). The performance of the bin improved with the presence of 60 holes per side (240 in all) for ventilation (Fig. 2).

What about costs?

- Cost of yellow top: $10.50
- Cost of bin with lid: $15.00
- Cost of mesh + glue: $5.00

  **TOTAL:** $30.50 per trap (durability: several years)

- Trap density at Busby farm (blueberry): 7 per acre
- If a 1-acre blueberry orchard has a mass trapping system in place with 7 traps, then the total cost of traps will be: $213.50 (one-time investment)
- Annual cost of 14 lures ($4.25 each), including one replacement: $59.50.

- Cost of spraying PyGanic 5.0 EC against Japanese beetle in one-acre plot: **$77 PER APPLICATION** (high rate). Cost is for insecticide only.
- Cost of applying PyGanic twice a week for 6 weeks: $924

*Use of traps also means that negative impacts of insecticide application on non-targets will be avoided.*
Perimeter Strategy: “Complete Block” used (Ideal)

Diagram 1: “force-field”
How not to trap Japanese Beetles!

Goal: Draw JB away from cash crop—not toward it!

Diagram 2: Poor trap placement
How to Build a Mass Trapping System for Japanese Beetles

Step 1: Drill small holes in bottom of the 32 gallon bin with 3/8ths inch bit to allow rain water to drain.

Step 2: Cut a 5 by 15 inch rectangle out of cardboard. Use as a template to draw 2 windows (one on each side of bin).

Step 3: Use an aviation “tin-snip” tool to cut out the window you traced with permanent marker.

Step 4: The front and back of bin should look like this.

Step 5: Stand the bin on its base.

Step 6: Use sandpaper to sand the inside edges of the windows. This will allow the glue to adhere to the plastic. WARNING: Do not use hot glue because it will melt outside in the summer heat!

Step 7: Cut a 7 by 20 inch rectangle out of cardboard. Use this template to cut out 2 window screens (with scissors).

Step 8: Lay the bin on one side and secure the aluminum screen inside with Duck tape. Glue the screen to the bin and allow glue to dry overnight. Gorilla glue is best—you can also use epoxy or E6000.

Step 9: Both steel mesh windows in place.
How to Build a Mass Trapping System for Japanese Beetles

Step 1: At the center of the lid, draw an “X” that is 4 inches by 4 inches. Draw a 2 inch circle around the center.

Step 2: Drill a large hole in the center and use that as a starting point to cut out the “X” & circle shape you drew.

Step 3: It should look like this.

Step 4: Push the base of yellow commercial top through the slots you made.

Step 5: Peel the silver tab off of lure, remove rubber pheromone stopper, and place in cutout hole.

Step 6: Make a perimeter of traps approximately 15 meters away from the crop you want to protect. Intercept incoming beetles from the side of highest pressure or place traps upwind. Remember, Japanese beetles emerge from the pasture — traps positioned between the pasture and cash crop will intercept incoming beetles. This is a preventative control option, so deploy traps before beetles land on your crop because they are reluctant to leave once they find a food source. Trap tops & lures can be purchased from: www.greatlakesipm.com

To keep the bin upright, we used two 4 ft. metal “electric fence posts” slid through the handles (They only cost $1.50 each). You can also use Rebar or simply hammer a tomato stake in the ground. Then, wrap a piece of string or wire around the bin to secure it.
Conclusions

1) Mass trapping may offer a cost effective organic control option
2) Environmentally friendly approach that is pesticide-free
3) Potential benefits of composting beetle biomass
4) Works autonomously and suppresses adult beetles from cropped areas
Issues with biological controls:

1) Cost: Expensive to make spores in lab, labor to apply/re-apply
2) Studies say “ineffective,” partial control, resistance (3rd instar)
3) Only treats area applied — does not address incoming pressure
4) Infected larvae continue feeding & causing damage (non-targets)

Thank you!

Project led by Dr. Jaime C. Pinero, Lincoln University State IPM Specialist.

We thank Junille Baker, Tina Coombs, Jason Miller, Traron Shivers, Binita Shrestha, and Jacob Wilson for technical assistance.
